14 **Author contributions**

15 The present investigation was conducted at the Sports and Exercise Science Research Centre  
16 physiology laboratory, located on the Whitelands campus at the University of Roehampton.

17 Ralph Gordon, Neale Tillin and Christopher Tyler contributed to the conception and design of  
18 the study. Ralph Gordon, Neale Tillin and Christopher Tyler contributed to the acquisition,  
19 analysis and interpretation of the data. Ralph Gordon drafted the manuscript and Neale Tillin  
20 and Christopher Tyler made critical revisions. Ralph Gordon, Neale Tillin and Christopher  
21 Tyler have approved the final version of the manuscript. Ralph Gordon, Neale Tillin and

22 Christopher Tyler agree to be accountable for all aspects of the presented work. Ralph Gordon,  
23 Neale Tillin and Christopher Tyler qualify for authorship.

## 24 **Abstract**

25 The effect of localised head and neck per-cooling on central and peripheral fatigue during high  
26 thermal strain was investigated. Fourteen participants cycled for 60 min at 50%  $\dot{V}O_{2peak}$  on  
27 three occasions: CON (18°C), HOT (35°C) and HOT with cooling (HOT<sub>cooling</sub>). Maximal  
28 voluntary force (MVF) and central activation ratio (CAR) of the knee extensors were measured  
29 every 30s during a sustained maximal voluntary contraction (MVC). Triplet peak force was  
30 measured following cycling, pre-and post the MVC. Rectal temperatures were higher in  
31 HOT<sub>cooling</sub> ( $39.2 \pm 0.6^\circ\text{C}$ ) and HOT ( $39.3 \pm 0.5^\circ\text{C}$ ) than CON ( $38.1 \pm 0.3^\circ\text{C}$ ;  $P < 0.05$ ). Head  
32 and neck thermal sensation was similar in HOT<sub>cooling</sub> ( $4.2 \pm 1.4$ ) and CON ( $4.4 \pm 0.9$ ;  $P > 0.05$ )  
33 but lower than HOT ( $5.9 \pm 1.5$ ;  $P < 0.05$ ). MVF and CAR were lower in HOT than CON  
34 throughout the MVC ( $P < 0.05$ ). MVF and CAR were also lower in HOT<sub>cooling</sub> than CON at 5,  
35 60, and 120s, but similar at 30 and 90s into the MVC ( $P > 0.05$ ). Furthermore, they were greater  
36 in HOT<sub>cooling</sub> than HOT at 30s, whilst triplet peak force was preserved in HOT post-MVC.  
37 These results provide evidence that central fatigue following exercise in the heat is partially  
38 attenuated with head and neck cooling, which may be at the expense of greater peripheral  
39 fatigue.

## 40 **Novelty**

- 41 • Central fatigue was greatest during hyperthermia
- 42 • Head and neck cooling partially attenuated the greater central fatigue in the heat
- 43 • Per-cooling led to more voluntary force production and more peripheral fatigue

44 **Key words**

45 Hyperthermia, cooling, central activation, maximal voluntary contraction, peripheral fatigue,  
46 exercise.

47 **Introduction**

48 Sub-maximal endurance exercise performance is impaired in hot environmental conditions  
49 (Galloway & Maughan, 1997). The reasons for the impaired performance are yet to be fully  
50 elucidated but may be partly due to neuromuscular fatigue. Neuromuscular fatigue is measured  
51 as a decline in maximal voluntary force (MVF) production and may be caused by mechanisms  
52 distal (peripheral fatigue; Allen et al., 2008) and/or proximal (central fatigue) to the  
53 neuromuscular junction (Gandevia, 2001). Peripheral fatigue is typically measured as a  
54 decrease in the involuntary contractile forces, reflecting a reduction in the available force  
55 capacity of muscle (Allen et al., 2008). Central fatigue is often measured as a larger decline in  
56 maximal voluntary- relative to involuntary contractile forces (Todd et al., 2005), representing  
57 a reduced ability of the central nervous system to drive the available force capacity of muscle.

58 Neuromuscular fatigue is exacerbated when thermal strain increases (core body temperature  $\geq$   
59 38.5°C) and evidence suggests that this is due to increased central fatigue (Nybo & Nielsen,  
60 2001a, Périard et al., 2014). Specifically, observations of larger reductions in MVF during  
61 sustained (45-120s) maximal voluntary contractions (MVC) following exercise-induced  
62 hyperthermia compared to control conditions, have been accompanied by larger declines in the  
63 central activation ratio (CAR; ratio of MVF- to the sum of MVF and superimposed-involuntary  
64 forces; Shield & Zhou, 2004) during the sustained MVCs (Nybo & Nielsen, 2001a, Périard et  
65 al., 2014). Similar evidence of reductions in MVF and CAR during sustained MVCs have also  
66 been observed during passively induced thermal strain (Todd et al., 2005, Périard et al., 2014,

67 Racinais et al., 2008). Despite consistent evidence of greater central fatigue during high thermal  
68 strain compared to control conditions, it is unclear how hyperthermia effects the development  
69 of peripheral fatigue during fatiguing exercise. The degree of peripheral fatigue recorded in a  
70 fatiguing contraction to task failure is directly proportional to the absolute force task (Burnley  
71 et al., 2012). It is therefore conceivable that the hyperthermia-induced reduction in neural drive  
72 leading to lower force outputs during fatiguing contractions would result in lower peripheral  
73 fatigue, but this hypothesis has not been tested.

74 Hyperthermia-induced central fatigue may be attenuated by externally cooling the head and/or  
75 neck region. Neck cooling has been demonstrated to improve time trial running performance  
76 and time to exhaustion (by ~6 – 13%; Tyler & Sunderland, 2011b) in hot environmental  
77 conditions, without influencing thermoregulatory or cardiovascular strain (Tyler &  
78 Sunderland, 2011b, Tyler et al., 2010, Tyler & Sunderland, 2011a). The improvement may be  
79 due to the neck cooling reducing the temperature of the thermoregulatory centre at the brain  
80 (Racinais et al., 2008), but is more likely to be improved perception of thermal strain (Tyler &  
81 Sunderland, 2011b, Nielsen & Jessen, 1992), permitting the participant to tolerate higher core  
82 temperatures and/or select a faster pace for the same core temperature (Tyler & Sunderland,  
83 2011b). By improving perceptions of thermal strain with head and neck cooling, it is  
84 conceivable that central fatigue may also be reduced, which may attenuate the decline in MVF  
85 during a sustained MVC following exercise in the heat. Racinais et al., (2008) observed no  
86 effect of head and neck cooling on central fatigue during a sustained contraction when  
87 hyperthermic; however, hyperthermia was induced passively, and rectal temperature remained  
88 < 39°C. Given the detrimental effects of hyperthermia on neuromuscular fatigue appear greater  
89 following exercise- vs. passively-induced hyperthermia (Périard et al., 2011), and greater at  
90 core temperatures > 39 °C vs < 39°C (Périard et al., 2014, Thomas et al., 2006), it is possible

91 that the benefits of head and neck cooling may only be measurable at exercise-induced core  
92 temperatures  $> 39^{\circ}\text{C}$ .

93 The aim of this study was to investigate the effects of cooling the head and neck whilst cycling  
94 in the heat to core body temperatures  $> 39^{\circ}\text{C}$  on central and peripheral fatigue. We  
95 hypothesized that: (i) hyperthermia induced by cycling in the heat would augment  
96 neuromuscular fatigue due to greater central fatigue, but this would reduce peripheral fatigue;  
97 and (ii) that head and neck cooling during and after cycling in the heat would attenuate the  
98 greater central fatigue caused by hyperthermia, but at the expense of greater peripheral fatigue.

## 99 **Methods**

### 100 **Participants**

101 Fourteen healthy, physically active males volunteered to participate. Their mean ( $\pm$  SD) age,  
102 body mass, percentage body fat, stature, and relative peak oxygen uptake ( $\dot{V}\text{O}_{2\text{peak}}$ ) were; 25.3  
103  $\pm 3.2$  years, 77.4  $\pm 11.0$  kg, 15.9  $\pm 5.8\%$ , 180.6  $\pm 6.6$  cm, and 52.9  $\pm 5.8$  mL $\cdot$ kg $^{-1}\cdot$ min $^{-1}$ ,  
104 respectively. Participants were informed of any risks and discomforts associated with the  
105 experiment before giving their written and oral informed consent. Participants visited the  
106 laboratory on five occasions (two familiarisations and three experimental sessions) at the same  
107 time of day, each separated by  $7 \pm 2$  days. A health screening procedure was repeated prior to  
108 each laboratory visit to assess the health status of the participant (ACSM, 1998). All  
109 experimental procedures were approved by the Ethical Advisory Committee of the University  
110 of Roehampton and in accordance with the declaration of Helsinki.

111 **Pre-experimental sessions**

112 In the first familiarisation session participants had their stature and body mass recorded and  
113 underwent body composition assessment using air plethysmography (BodPod, Cosmed, Italy)  
114 before performing an incremental maximal power test (Kuipers et al., 1985) on a cycle  
115 ergometer (Monark, 874E, Monark, Vansbro, Sweden) to determine maximum power output  
116 ( $W_{\max}$ ) and  $\dot{V}O_{2\text{peak}}$ . Participants were then familiarised with the neuromuscular function  
117 measurements (isometric MVCs and electrically evoked involuntary contractions of the knee  
118 extensors of the preferred leg). The second familiarisation session was identical to the  
119 experimental session completed in hot environmental conditions without cooling (see  
120 *Experimental sessions*), i.e. participants exercised in the heat and performed the neuromuscular  
121 function measurements whilst in a hyperthermic state. This second familiarisation session was  
122 deemed necessary from our pilot testing, which showed several participants were unable to  
123 complete a HOT protocol without prior familiarisation with exercising in the heat.

124 **Experimental sessions**

125 Participants wore the same exercise attire (shorts and T-shirt) for each session and were asked  
126 to abstain from strenuous physical activity and alcohol consumption 24h prior to each  
127 experimental visit. Upon arrival at the laboratory, participants were seated in the strength  
128 testing chair (see *Force section*) for instrumentation of electromyography (EMG) and electrical  
129 stimulation of the femoral nerve (see *Electrical stimulation*). Participants completed a series of  
130 warm-up contractions at incremental intensities from 20 – 90% of maximum perceived effort,  
131 followed by four MVCs (separated by ~1 min to allow adequate recovery) in which they were  
132 instructed to push as ‘hard’ as possible for 3 – 5s. A single twitch and triplet contraction (see  
133 *Electrical stimulation section*), separated by 2s, were superimposed at the plateau of the force-  
134 time curve (~1s after contraction onset) during the second and fourth MVCs.

135 Following the MVCs, the participants remained at rest whilst a train of involuntary contractions  
136 were elicited, consisting of one twitch, one triplet, one twitch, and one triplet, each separated  
137 by 2s. This same train of four involuntary contractions was then used throughout the protocol  
138 where electrical stimulation occurred (Figure. 1).

139 All neuromuscular assessments were performed outside the environmental chamber, in a  
140 thermoneutral laboratory (~22°C). After completion of the initial (pre-cycling) neuromuscular  
141 assessments, participants emptied their bladders, recorded nude body mass (Seca, Robusta 813,  
142 Seca, Birmingham, UK), self-inserted a rectal thermistor, and moved into the walk-in  
143 environmental chamber (Weiss Technik Ltd, Wales, UK). When in the chamber, participants  
144 sat quietly in an upright position for ~5 min while being instrumented with skin thermistors.  
145 Once resting temperature, heart rate (HR), and perceptual measurements were recorded,  
146 participants began cycling at 50%  $W_{max}$  for 60 min, in one of three conditions (a different  
147 condition in each experimental session conducted in a randomized order); a thermoneutral  
148 control (CON; 18°C, 50% relative humidity (Rh)), hot (HOT; 35°C, 50% Rh), and HOT with  
149 head and neck cooling (HOT<sub>cooling</sub>). Head and neck cooling was achieved through a customised  
150 water-perfused hood and neck cooling system with inlet water temperature set to 3°C (Active  
151 Ice and Cool Flow Cooling System, Polar Product Inc., USA).

152 Once the 60 min cycling bout was completed, participants put on an impermeable rain jacket  
153 to restrict heat loss before leaving the climatic chamber and returned to the isometric strength  
154 testing chair (located ~5 m from the walk-in environmental chamber). During HOT<sub>cooling</sub>,  
155 participants continued to wear the head and neck cooling garments while performing the post  
156 cycling neuromuscular assessments. Participants were seated; securely fastened and re-  
157 instrumented as quickly as possible (transition time: ~5 min). Following this preparation, the  
158 stimulation train of four involuntary evoked contractions were elicited at rest to determine a  
159 change in baseline involuntary contractile properties following the cycle exercise (Figure. 1).

160 Five seconds after the last electrically evoked contraction, participants performed a sustained  
161 MVC in which they were instructed to push as hard as possible for 123s. The stimulation train  
162 was superimposed during the 123s MVC at 2, 27, 57, 87 and 117s (centre of the train coinciding  
163 with 5, 30, 60, 90, and 120s), and evoked again at rest 5s after the 123s MVC. Strong verbal  
164 encouragement was provided throughout, and participants were blinded to time during their  
165 efforts to avoid any pacing strategies. Refrigerated water was provided ad libitum throughout  
166 the trials.

## 167 **Measurements**

### 168 **Force**

169 All voluntary and involuntary isometric contractions of the knee extensors were conducted in  
170 a custom-built isometric strength testing chair (Maffiuletti et al., 2016). Participants were  
171 securely fastened with a waist belt and shoulder straps, with hip and knee angles fixed at 100°  
172 and 105° respectively (180° was full extension). An ankle strap, in series with a strain gauge  
173 load cell (Force Logic, FSB-1.5kN Universal Cell 1.5kN, Force Logic, Reading, UK), was  
174 secured 4 cm proximal to the medial malleolus with the load cell aligned perpendicular to the  
175 tibia during knee extension. The force signal was amplified (x375), interfaced with an  
176 analogue-to-digital converter (CED, Mirco3 1401, Cambridge Electrical Design, Cambridge,  
177 UK), and sampled at 2000 Hz with a personal computer using Spike2 software (Spike 2 Version  
178 8, Cambridge Electrical Design, Cambridge, UK). Real-time biofeedback of the force response  
179 was provided on a 127 cm television screen, directly in front of the isometric strength testing  
180 chair.

### 181 **EMG**

182 Surface EMG signals were recorded from the rectus femoris (RF), vastus lateralis (VL) and  
183 vastus medialis (VM) (Noraxon, TeleMYO DTS, Noraxon, Arizona, USA). Following

184 preparation of the skin (shaving, light abrasion and cleaning using 70% ethanol) two bipolar  
185 silver-silver-chloride gel-electrode configurations (2 cm diameter, and 2 cm inter-electrode  
186 distance; Noraxon, Dual Electrode, Noraxon, Arizona, USA) were placed: over the belly of  
187 each muscle (i.e., two EMG signals per muscle); in parallel to the presumed orientation of the  
188 muscle fibres; and at  $60 \pm 4\%$  (RF1),  $47 \pm 3\%$  (RF2),  $74 \pm 15\%$  (VL1),  $64 \pm 9\%$  (VL2),  $83 \pm$   
189  $19\%$  (VM1) and  $75 \pm 13\%$  (VM2) of the distance from the greater trochanter to the lateral  
190 knee-joint space. Once attached to the skin the electrodes remained in place for the duration of  
191 the experimental trial, with placement conducted by the same investigator throughout all trials.  
192 Each EMG signal was amplified (x500; 10-500 Hz bandwidth) and sampled (2000 Hz) in  
193 synchronisation with force via the same analogue-to-digital converter utilising Spike2  
194 software. In off-line analysis, the EMG signals were band-pass-filtered between 5 and 500 Hz  
195 using a fourth-order Butterworth digital filter and corrected for the 156 ms delay inherent in  
196 the Noraxon, TeleMYO DTS system. Signals collected during voluntary contractions were  
197 smoothed with a root mean squared (RMS) moving time window with a 500 ms epoch.

## 198 **Electrical stimulation**

199 Electrical square-wave pulses (0.2 ms duration) delivered over the femoral nerve (Digitimer,  
200 DS7AH Constant Current Stimulator, Digitimer, Hertfordshire, UK) were used to evoke twitch  
201 contractions, compound muscle action potentials (M-waves), and triplet contractions (3 pulses  
202 at 100 Hz). The anode (Rubber electrode 10 x 7 cm, EMS Physio Ltd, Oxfordshire, UK) was  
203 secured by surgical tape (Transpore 2.5 cm x 5 cm, 3M, UK) to the skin over the greater  
204 trochanter. The cathode stimulation probe (1 cm diameter tip; Digitimer, S1 Compex Motor  
205 PointPen, Digitimer, Hertfordshire, UK), which protruded 2 cm from the centre of a custom-  
206 built plastic base (4 x 3 cm) was placed over the femoral nerve in the femoral triangle. The  
207 greatest evoked peak twitch force in response to a submaximal current determined the precise  
208 placement of the cathode, where it was taped in place. The intensity of stimulation was then

209 progressively increased, until there was a plateau in both twitch peak force and peak-to-peak  
210 M-wave amplitude ( $M_{\max}$ ) at each EMG site. This intensity was increased by a further 20%  
211 (supra-maximal) to ensure all stimulations were eliciting a maximal involuntary response and  
212 kept constant thereafter for all twitch and triplet contractions. The cathode position was marked  
213 on the skin with permanent ink prior to the 60 min of cycling to ensure accurate relocation in  
214 the post-cycling neuromuscular function assessment.

### 215 **Skin and rectal temperature**

216 To assess rectal temperature ( $T_{re}$ ), a rectal thermistor (REC-U-VL30, Grant Instruments,  
217 Cambridge, UK) was self-inserted ~10 cm past the anal sphincter. Four skin thermistors (EUS-  
218 U-VL3-0, Grant Instruments, Cambridge, UK) were applied to the skin with a transparent  
219 dressing (Tegaderm, 6 x 7 cm, 3M, Minnesota, USA) and secured with surgical tape for the  
220 assessment of local skin temperature. Mean weighted skin temperature ( $\overline{T}_{sk}$ ) was calculated  
221 from the four skin sites located on the right side of the body (suprasternal notch and one each  
222 on the belly of the following muscles, flexi carpi radialis, gastrocnemius and rectus femoris)  
223 using the equation of Ramanathan (1964). Mean neck skin temperature ( $\overline{T}_{neck}$ ) was obtained  
224 from two thermistors placed either side of the spinal midline at approximately the 3rd/4th  
225 cervical vertebrae. All temperature measurements were recorded at: baseline immediately prior  
226 to the cycling, 5 min intervals during cycling, and immediately before and after the 123s MVC.

### 227 **Perceptual measurements and heart rate**

228 Rating of perceived exertion (RPE), whole body thermal sensation (TS), thermal sensation of  
229 the head and neck ( $TS_{neck}$ ) and HR were recorded at the same time as temperature data. RPE  
230 was rated using a fifteen-point scale from 6 (at rest) to 20 (maximal exertion; Borg, 1982).  
231 Thermal sensation was rated using a nine-point scale from 0 (unbearably cold) to 8 (unbearably  
232 hot) with 4 as neutral (Young et al., 1987). HR was recorded with a heart rate monitor, secured

233 with strap and worn by the participant in contact with the skin (Polar F3, Polar Electro, UK,  
234 Ltd).

## 235 **Neuromuscular Data Analysis**

### 236 **Pre-cycling**

237 Pre-cycling MVF was defined as the greatest voluntary (i.e., not due to superimposed twitch  
238 or triplet) force recorded in any of the MVCs performed prior to the 60 min cycling. To assess  
239 central drive at/near MVF, the CAR was determined as voluntary force at the point of triplet  
240 stimulation divided by the sum of voluntary force at triplet stimulation and superimposed triplet  
241 force (total muscle force; Kent-Braun & Le Blanc, 1996), and averaged across the two MVCs  
242 in which superimposed stimulation occurred. Central drive was also assessed from RMS EMG  
243 at MVF (or at the point closest to MVF without influence of artefact from electrical  
244 stimulation), normalised to the maximal M-wave ( $M_{\max}$ ; determined from the average of the  
245 two M-waves evoked during the MVCs), and averaged across the six EMG sites to give a value  
246 for the whole quadriceps muscle ( $EMG_{MVF}$ ).

### 247 **Stimulation at Rest**

248 For each stimulation train elicited at rest (i.e., pre-cycling, pre-123s MVC, and post-123s  
249 MVC) the following variables were averaged across the two twitch or two triplet contractions  
250 in that stimulation train:  $M_{\max}$  (from the twitch); triplet peak force (PF), triplet peak rate of  
251 force development (pRFD; determined with a 50 ms epoch) and triplet half-relaxation time  
252 (HRT).

### 253 **123s MVC**

254 CAR was averaged from the two superimposed triplets, and  $M_{\max}$  from the two superimposed  
255 twitch contractions in each stimulation train elicited during the 123 s MVC (i.e., at 5, 30, 60,

256 90 and 120s). MVF and  $EMG_{MVF}$  were also recorded at 5, 30, 60, 90 and 120s, where  $EMG_{MVF}$   
257 was obtained by normalising RMS EMG at the superimposed  $M_{max}$ , before averaging across  
258 the six EMG sites.

## 259 **Statistical analyses**

260 Descriptive data are reported as mean  $\pm$  standard deviation (SD). Data were assessed for  
261 normality of distribution with the Shapiro-Wilk test. Two-way repeated measures ANOVAs  
262 evaluated the effect of condition by time on all dependent variables. Specifically, ANOVAs  
263 for: MVF, CAR, and  $EMG_{MVF}$  included 3 conditions (CON,  $HOT_{cooling}$  and HOT) by 6 time  
264 points (baseline pre-cycling, and at 5, 30, 60, 90, and 120s during the 123s MVC). ANOVAs  
265 for triplet variables and  $M_{max}$  evoked at rest included 3 conditions x 3 time points (baseline pre-  
266 cycling, pre-123s MVC, and post-123s MVC). ANOVAs for TS,  $TS_{neck}$ , HR,  $T_{re}$ ,  $\overline{T}_{neck}$ , and  
267  $\overline{T}_{sk}$  included 3 conditions by 13 time points (12 time points for RPE; baseline pre-cycling and  
268 5 min intervals throughout cycling). Violations of sphericity were corrected for using the  
269 Greenhouse-Geisser adjustment when appropriate. Following a significant F value, pairwise  
270 differences between conditions were identified using stepwise Bonferroni-corrected paired t-  
271 tests, at each individual time point for all the above dependant variables. The significance level  
272 was set at  $P < 0.05$ . Statistical analysis was completed using SPSS version 21 (SPSS Inc.,  
273 Chicago, IL). Cohen's Effect size ( $d$ ) for paired comparisons were calculated (Cohen, 1988).

## 274 **Results**

### 275 **Temperature**

276 There was a main effect of time ( $P < 0.001$ ) on  $T_{re}$ ,  $\overline{T}_{sk}$  and  $\overline{T}_{neck}$ , which all increased  
277 throughout the cycling in all conditions. There were also main effects of condition and

278 condition by time interaction effects on these variables ( $P < 0.001$ ).  $T_{re}$  was lower in CON than  
279 HOT and  $HOT_{cooling}$  after 30 min of cycling ( $P < 0.05$ ;  $0.38 \geq d \leq 7.96$ ; Figure. 2A), and  $\overline{T}_{sk}$   
280 was lower in CON than HOT and  $HOT_{cooling}$  at all measured time points throughout the trial ( $P$   
281  $< 0.05$ ;  $0.37 \geq d \leq 7.38$ ; Figure. 2B). However,  $T_{re}$  and  $\overline{T}_{sk}$  were similar throughout HOT and  
282  $HOT_{cooling}$  ( $P > 0.05$ ;  $0.01 \geq d \leq 0.65$ ).  $\overline{T}_{neck}$  was similar in CON and  $HOT_{cooling}$  ( $P > 0.05$ ;  
283  $0.01 \geq d \leq 0.41$ ; Figure. 2C) at all measured time points, except at baseline where it was lower  
284 in CON ( $P < 0.001$ ;  $d = 2.11$ ), and post 123s MVC where it was lower in  $HOT_{cooling}$  ( $P = 0.004$ ;  
285  $d = 1.36$ ).  $\overline{T}_{neck}$  was greater in HOT than both CON ( $P < 0.05$ ;  $3.42 \geq d \leq 6.66$ ) and  $HOT_{cooling}$   
286 ( $P < 0.05$ ;  $2.48 \geq d \leq 6.00$ ; Figure. 2C) at all measured time points.

### 287 **Perceptual measures and Heart Rate**

288 There was a main effect of time ( $P < 0.001$ ) on TS and  $TS_{neck}$ , which both increased throughout  
289 all conditions. There were also main effects of condition ( $P < 0.001$ ) for both variables, but not  
290 condition by time interaction effects ( $P > 0.05$ ). TS was lower throughout CON than both HOT  
291 ( $P < 0.05$ ;  $0.73 \geq d \leq 3.03$ ) and  $HOT_{cooling}$  ( $P < 0.05$ ;  $0.72 \geq d \leq 2.29$ ), but similar in HOT and  
292  $HOT_{cooling}$  ( $P > 0.05$ ;  $-0.84 \geq d \leq -0.03$ ) at all measured time points (Figure. 3C). On the other  
293 hand,  $TS_{neck}$  was similar in CON and  $HOT_{cooling}$  ( $P > 0.05$ ;  $0.04 \geq d \leq 0.85$ ), but lower in both  
294 these conditions compared to HOT ( $P < 0.05$ ;  $0.30 \geq d \leq 2.19$ ), at all measured time points  
295 (Figure. 3D).

296 RPE and HR were effected similarly by time ( $P < 0.001$ ), condition ( $P < 0.001$ ), and condition  
297 by time ( $P < 0.05$ ). Specifically, RPE and HR increased throughout the cycling in all conditions  
298 but were both greater in HOT ( $P < 0.05$ ;  $0.56 \geq d \leq 2.34$ ) and  $HOT_{cooling}$  ( $P < 0.05$ ;  $0.50 \geq d \leq$   
299  $2.10$ ) than CON after the first 5 min, and similar for HOT and  $HOT_{cooling}$  ( $P > 0.05$ ;  $0.01 \geq d \leq$   
300  $0.20$ ) at all measured time points (Figure. 3A and 3B).

## 301 MVC Measures

302 There was a main effect of time ( $P < 0.001$ ) on MVF, which declined throughout the 123s  
303 MVC in all conditions. There was also a main effect of condition ( $P < 0.001$ ) and a condition  
304 by time interaction effect ( $P = 0.043$ ). Whilst MVF was similar in all conditions pre-cycling  
305 ( $P > 0.05$ ;  $0.06 \geq d \leq 0.17$ ; Figure. 4A), it was 14-35% greater in CON than HOT ( $P < 0.05$ ;  
306  $0.42 \geq d \leq 0.97$ ; Figure. 4A) at all measured time points during the 123s MVC post-cycling.  
307 Whilst MVF in CON was 9-38% greater than in HOT<sub>cooling</sub> at 5, 60, and 120s ( $P < 0.05$ ;  $0.27 \geq$   
308  $d \leq 1.34$ ), it was similar between these conditions at 30s ( $P = 0.39$ ;  $d = 0.23$ ) and 90s ( $P = 0.74$ ;  
309  $d = 0.47$ ; Figure. 4A) into the 123s MVC. MVF in HOT<sub>cooling</sub> was 4-12% greater than HOT  
310 throughout the 123s MVC and although these differences were not significant at any time point  
311 ( $P > 0.05$ ;  $0.12 \geq d \leq 0.37$ ), there was a small beneficial effect at 30s ( $P = 0.072$ ;  $d = 0.32$ ).

312 Similar to MVF, there was a main effect of time ( $P < 0.001$ ) on CAR, which decreased  
313 throughout the 123s MVC, condition ( $P < 0.001$ ), and a condition by time interaction effect ( $P$   
314  $= 0.017$ ). At baseline pre-cycling, CAR was similar between conditions ( $P > 0.05$ ;  $0.02 \geq d \leq$   
315  $0.10$ ); however, during the 123s MVC post-cycling CAR was 10-30% greater in CON than  
316 HOT at all measured time points ( $P < 0.05$ ;  $0.63 \geq d \leq 1.01$ ; Figure. 4B). In contrast, CAR  
317 during the 123s MVC was only greater (6-24%) in CON than HOT<sub>cooling</sub> at 5, 60 and 120s into  
318 the 123s MVC ( $P < 0.05$ ;  $0.47 \geq d \leq 0.79$ ; Figure. 4B), but similar between these conditions at  
319 30s ( $P = 0.99$ ;  $d = 0.20$ ) and 90s ( $P = 0.174$ ;  $d = 0.51$ ). Furthermore, CAR during the 123s  
320 MVC in HOT<sub>cooling</sub> was 4-15% greater than HOT at each time point, and this difference was  
321 statistically significant at 30s ( $P = 0.04$ ;  $d = 0.38$ ; Figure. 4B).

322 EMG<sub>MVF</sub> was similar in all conditions at baseline pre-cycling ( $P > 0.05$ ;  $0.07 \geq d \leq 0.28$ ; Figure.  
323 4C) but there was a main effect of time ( $P < 0.001$ ) and EMG<sub>MVF</sub> decreased throughout the  
324 123s MVC. There was also a main effect of condition ( $P < 0.001$ ), but no condition by time

325 interaction effect ( $P = 0.27$ ), caused by  $EMG_{MVF}$  in CON being greater than HOT at 5 and 30s  
326 ( $P < 0.05$ ;  $0.76 \geq d \leq 0.78$ ) and greater than  $HOT_{cooling}$  at 5 and 60s ( $P < 0.05$ ;  $0.56 \geq d \leq 0.85$ ;  
327 Figure. 4C) during the 123s MVC.  $EMG_{MVF}$  in  $HOT_{cooling}$  and HOT was similar throughout  
328 the 123s MVC ( $P > 0.05$ ;  $0.03 \geq d \leq 0.32$ ).

### 329 **Resting Evoked Measurements**

330 There was a main effect of time on PF, pRFD, and HRT ( $P < 0.05$  for all). There was also a  
331 main effect of condition ( $P < 0.05$ ) on these variables and a condition by time interaction effect  
332 for pRFD ( $P < 0.001$ ). The pattern of change for PF, pRFD and HRT was similar for all three  
333 conditions. Specifically, PF ( $P < 0.001$ ;  $-1.60 \geq d \leq -1.25$ ) and pRFD ( $P < 0.001$ ;  $-1.35 \geq d \leq -$   
334  $0.54$ ), decreased, and HRT was unchanged from pre- to post-cycling, pre-123s MVC ( $P = 0.12$ ;  
335  $-0.68 \geq d \leq -0.29$ ; Table 1). From pre- to post-123s MVC, PF decreased ( $P = 0.002$ ;  $-1.10 \geq d$   
336  $\leq -0.76$ ), and HRT increased ( $P < 0.001$ ;  $1.02 \geq d \leq 1.53$ ), whilst pRFD ( $P = 0.054$ ;  $-0.74 \geq d$   
337  $\leq -0.48$ ), was unchanged, in all conditions. Between conditions, PF, pRFD, and HRT were  
338 similar at baseline ( $P > 0.05$ ;  $0.01 \geq d \leq 0.16$ ). However, pRFD was lower in CON compared  
339 to either HOT or  $HOT_{cooling}$  following cycling, both pre- ( $P < 0.05$ ;  $0.45 \geq d \leq 0.70$ ) and post-  
340 the 123s MVC ( $P < 0.05$ ;  $0.75 \geq d \leq 0.90$ ). PF was greater and HRT shorter in HOT compared  
341 with CON post-123s MVC (PF;  $P < 0.05$ ;  $d = 0.47$ ; HRT;  $P < 0.05$ ;  $d = -1.01$ ). No other  
342 differences between conditions were observed ( $P > 0.05$ ).

343 There was a main effect of time ( $P < 0.001$ ) on  $M_{max}$  at rest, which decreased progressively at  
344 each time point (pre-cycling, pre-MVC and post-MVC; Table 1). There was no main effect of  
345 condition ( $P = 0.73$ ) or condition by time interaction ( $P = 0.18$ ).

346 **Discussion**

347 The present study assessed the effects of head and neck per-cooling whilst cycling in the heat  
348 on central and peripheral fatigue during subsequent fatiguing exercise. As expected, cycling  
349 during compensable heat stress ( $T_{re} \sim 39.3^{\circ}\text{C}$  at the start of the 123s MVC) resulted in greater  
350 declines in MVF associated with greater central fatigue (reduced CAR) during the 123s MVC  
351 following cycling, compared to CON. Our results provide some, albeit in-conclusive, evidence  
352 that head and neck cooling may attenuate the effects of hyperthermia on central fatigue. Whilst  
353 MVF during the 123s MVC in  $\text{HOT}_{\text{cooling}}$  was not statistically different to HOT, it was  
354 statistically similar to CON at 30 and 90s. Furthermore, CAR was greater in  $\text{HOT}_{\text{cooling}}$  than  
355 HOT at 30s and similar between  $\text{HOT}_{\text{cooling}}$  and CON at 30 and 90s. The potential attenuation  
356 of central fatigue with head and neck cooling may be due to improved perception of thermal  
357 strain of the head and neck, evidenced by lower  $\text{TS}_{\text{neck}}$ , in  $\text{HOT}_{\text{cooling}}$  compared with HOT,  
358 despite almost identical responses between these conditions in perceived (TS) and actual ( $T_{re}$ )  
359 thermal strain, cardiovascular strain (HR), and RPE. Interestingly, whilst evoked PF and HRT  
360 were similar between all three conditions pre- the 123s MVC; immediately after the 123s MVC,  
361 PF was lower and HRT longer in CON compared to HOT but similar between CON and  
362  $\text{HOT}_{\text{cooling}}$ . This suggests there was lower peripheral fatigue in HOT but not  $\text{HOT}_{\text{cooling}}$ ,  
363 compared to CON, likely due to the greater central fatigue and thus lower forces in HOT.

364 As reported elsewhere (Tyler & Sunderland, 2011b, Tyler et al., 2010, Tyler & Sunderland,  
365 2011a, Sunderland et al., 2015), cooling the head and neck had no effect on physiological ( $T_{re}$ ,  
366  $\overline{T}_{sk}$ , HR) or whole body perceptual (TS, RPE) strain and exertion, which were similar between  
367 HOT and  $\text{HOT}_{\text{cooling}}$ , and greater in both HOT conditions compared to CON. However, the  
368 head and neck cooling was effective at reducing  $\overline{T}_{\text{neck}}$  and  $\text{TS}_{\text{neck}}$  to CON values in  $\text{HOT}_{\text{cooling}}$

369 at all time points except baseline, where  $\overline{T}_{\text{neck}}$  was lower in CON, and post MVC when  $\overline{T}_{\text{neck}}$   
370  $\overline{T}_{\text{neck}}$  was lower in HOT<sub>cooling</sub>. Reductions in  $\overline{T}_{\text{neck}}$  and TS<sub>neck</sub> with head and neck cooling when  
371 exercising in the heat have been shown to benefit endurance performance (Tyler & Sunderland,  
372 2011b), so it is conceivable they may have benefited neuromuscular performance in the current  
373 study.

374 Both MVF and CAR were similar between conditions at baseline, pre-cycling, but both  
375 decreased following the cycling, at 5s into the 123s MVC in all conditions. Thus, the cycling  
376 induced central fatigue, which likely contributed to the decline in MVF, in all conditions.  
377 However, both MVF and CAR at 5s into the 123s MVC post-cycling were greater in CON than  
378 either HOT or HOT<sub>cooling</sub>, demonstrating greater central fatigue and thus a greater reduction in  
379 MVF, induced by hyperthermia. Furthermore, MVF and CAR continued to decline throughout  
380 the 123s MVC in all conditions but remained greater in CON than HOT at all measured time  
381 points, and greater in CON than HOT<sub>cooling</sub> at 5, 60, and 120s. These results are consistent with  
382 previous studies showing greater central fatigue causing greater reductions in MVF in  
383 hyperthermic vs. control conditions, where hyperthermia was induced either actively (Nybo &  
384 Nielsen, 2001a, Périard et al., 2014, Périard et al., 2011) or passively (Todd et al., 2005, Périard  
385 et al., 2014, Racinais et al., 2008, Périard et al., 2011). However, in the current study, MVF  
386 and CAR were similar between HOT<sub>cooling</sub> and CON at 30 and 90s and there were small effects  
387 for them to be larger in HOT<sub>cooling</sub> compared to HOT at 30s, during the 123s MVC. While these  
388 effects were small, the authors acknowledge there is some variability to the data, and it is not  
389 clear why per-cooling had an effect specifically at 30 and 90s during the sustained isometric  
390 contraction and not at other discrete time-points. It is plausible, however, over time during a  
391 long-distance event the cumulative small effect of per-cooling could accumulate to provide  
392 some benefit to performance.

393 The mechanisms of increased central fatigue in hyperthermic conditions are thought to be  
394 multifaceted with increases in brain temperature (Caputa et al., 1986), reductions in cerebral  
395 blood flow (Nybo & Nielsen, 2001b), inability to increase motor unit firing rate to  
396 accommodate faster muscle relaxation (Todd et al., 2005), and reductions in cerebral dopamine  
397 (Meeusen & Roelands, 2017) all potential contributing factors . Hyperthermia progressively  
398 impairs neuromuscular performance (Morrison et al., 2004) but the present study shows that  
399 cooling the head and neck may attenuate this reduction without effecting core body  
400 temperature. The exact mechanisms of the improved neuromuscular performance with head  
401 and neck cooling remain unclear but may be associated with reducing the temperature of the  
402 carotid blood destined for the brain (Zhu, 2000); however, others have suggested direct cooling  
403 of the brain is unlikely (Nybo et al., 2002). In the present study, improved thermal sensation of  
404 the head and neck from cooling, may have attenuated typical hyperthermia-induced reductions  
405 in brain activity (Xue et al., 2018), cortical somatosensory processing (Nakata et al., 2017)  
406 and/or dopamine neuron activation (Hasegawaa et al., 2000). In addition, head cooling can  
407 protect some functions of cognition in the heat (Racinais et al., 2008) and collectively, these  
408 factors may attenuate reductions in arousal (Nielsen et al., 2001). An increased state of arousal  
409 by alleviating local thermal sensation, could have translated into higher levels of motivation  
410 and greater voluntary neural activation of the central nervous system.

411  $EMG_{MVF}$  (normalised to  $M_{max}$ ) decreased throughout the 123s MVC in all conditions, which is  
412 consistent with the declines in CAR, and demonstrates central fatigue during the sustained  
413 contractions. However, the condition effects on normalised  $EMG_{MVF}$  were not as noticeable as  
414 they were for CAR. Specifically,  $EMG_{MVF}$  was only greater in CON than HOT (5 and 30s) or  
415  $HOT_{cooling}$  (5 and 60s) at 2/5 time points during the 123s MVC and was similar between HOT  
416 and  $HOT_{cooling}$  at all measured time points. Périard et al., (2014) also reported more noticeable  
417 effects of hyperthermia on CAR compared to  $EMG_{MVF}$  normalised to  $M_{max}$ , observing greater

418 reductions in CAR during a sustained contraction in hyperthermia vs. control conditions, but  
419 no condition effects on normalised  $EMG_{MVF}$ . Thus, EMG amplitude does not appear to be as  
420 sensitive as CAR to the effects of hyperthermia (or head and neck cooling when hyperthermic)  
421 on central drive during fatiguing exercise. This is likely due to the large variability inherent in  
422 EMG amplitude (Buckthorpe et al., 2012), in spite of the steps taken in the current study to  
423 improve reliability, such as recording EMG amplitude from two distinct sites on each muscle  
424 (Balshaw et al., 2017), and normalising EMG amplitude to  $M_{max}$  (Buckthorpe et al., 2012).

425 In addition to central fatigue, peripheral fatigue was also induced in all conditions, with  
426 decreases in evoked PF and pRFD from baseline to pre-123s MVC, following the cycling.  
427 Peripheral fatigue increased during the 123s MVC, as evidenced by the further declines in PF  
428 and the increase in HRT from pre- to post 123s MVC, in all conditions. These are typical  
429 responses known to occur in fatiguing exercise, due to metabolic perturbation interrupting  
430 excitation-contraction coupling (Allen et al., 2008). The effects of such metabolic perturbation  
431 on pRFD were mitigated in the HOT conditions, as evidenced by greater pRFD in HOT and  
432  $HOT_{cooling}$  compared to CON, both pre- and post- the 123s MVC, likely due to the higher  
433 muscle temperatures which are thought to improve the rate of myosin-actin cross bridge  
434 attachment (de Ruyter et al., 1999). The similar PF and HRT between conditions both pre-  
435 cycling and pre-123s MVC following the cycling, suggest the cycling induced similar  
436 peripheral fatigue in all conditions. However, post- the 123s MVC, PF was greater and HRT  
437 shorter in HOT, but not  $HOT_{cooling}$ , compared to CON. Thus, the 123s MVC induced less  
438 peripheral fatigue in HOT than CON, likely due to the greater central fatigue during the MVC  
439 in HOT, resulting in less force output and thus logically less metabolic perturbation.  
440 Furthermore, whilst head and neck cooling mitigated the effects of hyperthermia on central  
441 fatigue during the MVC, this appears to be at the expense of greater peripheral fatigue given  
442 the similarities in peripheral fatigue between  $HOT_{cooling}$  and CON. Work from Amann and

443 colleagues (Amann & Dempsey, 2008) suggests that during fatiguing self-paced exercise,  
444 central drive to the muscles is inhibited to limit peripheral fatigue to a task and individually  
445 specific critical threshold. Based on the results of the current study, we speculate that  
446 hyperthermia lowers this critical threshold of peripheral fatigue, though head and neck cooling  
447 may override this mechanism.

448 The  $M_{\max}$  evoked at rest declined in all conditions from pre- to post-cycling and declined  
449 further from pre- to post-123s MVC. A decline in  $M_{\max}$  with fatiguing exercise is well  
450 documented (Allen et al., 2008) and likely reflects an efflux of cellular  $K^+$  from the muscle  
451 fibres causing reduced muscle fibre excitability (Clausen et al., 2004). However, there were no  
452 condition effects (i.e., no effects of hyperthermia) on  $M_{\max}$ , which is inconsistent with studies  
453 showing  $M_{\max}$  to decrease with increased muscle or whole-body temperature (Périard et al.,  
454 2014, Racinais et al., 2008, Dewhurst et al., 2005), possibly due to reduced muscle fibre  
455 depolarisation time and associated decrease in cellular  $Na^+$  influx (Rutkove, 2001). It is  
456 possible the effects of fatiguing exercise on the  $M_{\max}$  in the three conditions of the current study  
457 may have masked any subtle effects of temperature on  $M_{\max}$ , and thus further research is  
458 required to better understand these mechanisms and their interactions.

459 One possible limitation of the current study was the need to assess neuromuscular function  
460 outside of the environmental chamber in temperate conditions. Core body temperature ( $T_{re}$ )  
461 was stable within each condition during the 123s MVC (Figure. 2A) but there was a decline in  
462  $\overline{T}_{neck}$  ( $-2.4 \pm 1.1^\circ C$ ) and  $TS_{neck}$  ( $-1.7 \pm 1.4$ ) in HOT during the 123s MVC.  $\overline{T}_{neck}$  and  $TS_{neck}$   
463 remained higher in HOT ( $35.0 \pm 1.1^\circ C$ ;  $5.8 \pm 1.5$ ; CON:  $34.0 \pm 0.6^\circ C$ ;  $5.1 \pm 0.8$ ; HOT<sub>cooling</sub>:  
464  $32.5 \pm 1.1^\circ C$ ;  $3.8 \pm 0.7$ ); however, because the effectiveness of any cooling intervention is  
465 dependent on the interaction between the magnitudes of cooling provided and thermal strain

466 experienced (for meta-analysis see Tyler et al., 2015) the natural reductions observed may have  
467 masked some of the cooling benefits.

468 In conclusion, our results provide evidence that head and neck cooling may attenuate some of  
469 the greater neuromuscular fatigue caused by hyperthermia, likely due to reduced central  
470 fatigue, although effects were small and not observable at all measured time points during a  
471 fatiguing activity. We also found that the greater central fatigue in hyperthermic conditions  
472 appears to reduce peripheral fatigue, but this response is mitigated with head and neck cooling.

### 473 **Acknowledgments**

474 The authors would like to thank all the volunteers who took part in this research for their time  
475 and effort. In addition, a special thank you to Jamie Hall and Kelly-Anne Clifford for their  
476 assistance with data collection.

596 **Table**

597 **Table 1.** Evoked triplet properties (PF (peak force); pRFD (peak rate of force development);  
 598 TPT (time to peak tension); HRT (half-relaxation time)) and maximal M-wave ( $M_{max}$ ) recorded  
 599 at different time points (pre-60 min cycling and pre- and post- a 123s MVC) in three  
 600 environmental conditions: control (CON), hot (HOT) and HOT with head and neck cooling  
 601 (HOT<sub>cooling</sub>). Data are means  $\pm$  SD ( $n = 14$ ).

	PF (N)	pRFD (N·s <sup>-1</sup> )	HRT (ms)	$M_{max}$ (mV)
<b>Pre-cycling</b>				
CON	432 $\pm$ 82	12060 $\pm$ 3475	75.0 $\pm$ 22.5	3.6 $\pm$ 0.9
HOT <sub>cooling</sub>	440 $\pm$ 65	11601 $\pm$ 3400	71.4 $\pm$ 22.3	3.6 $\pm$ 1.0
HOT	437 $\pm$ 70	11637 $\pm$ 2864	71.5 $\pm$ 23.4	3.7 $\pm$ 0.9
<b>Pre-123s MVC</b>				
CON	324 $\pm$ 77 †	8024 $\pm$ 2413 †	69.2 $\pm$ 17.1	3.1 $\pm$ 0.8 †

602 †; within condition paired differences ( $P < 0.05$ ), different from pre-cycling  
 603 ‡; within condition paired differences ( $P < 0.05$ ), different from pre- 123s MVC  
 604 \*; between condition paired differences at the same time point ( $P < 0.05$ ), different from CON  
 605

606 **Figure Legends**

607

608 Figure. 1. Schematic of the protocol conducted in three separate environmental conditions in  
 609 50% relative humidity: hot (HOT, 35°C), HOT with head and neck cooling (HOT<sub>cooling</sub>), and  
 610 control (CON, 18°C). Participants cycled for 60 min on a cycle ergometer at 50%  $\dot{V}O_{2peak}$ ,  
 611 between pre- and post-cycle assessments.

612

613

614

615

616

617

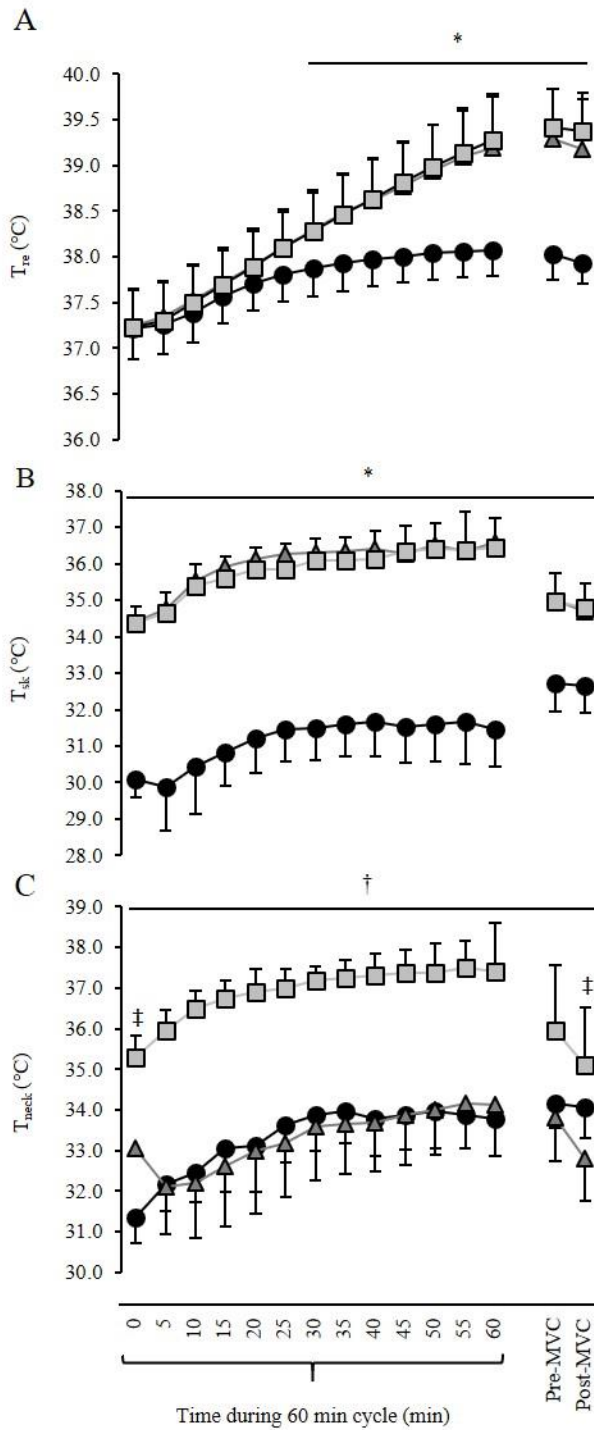

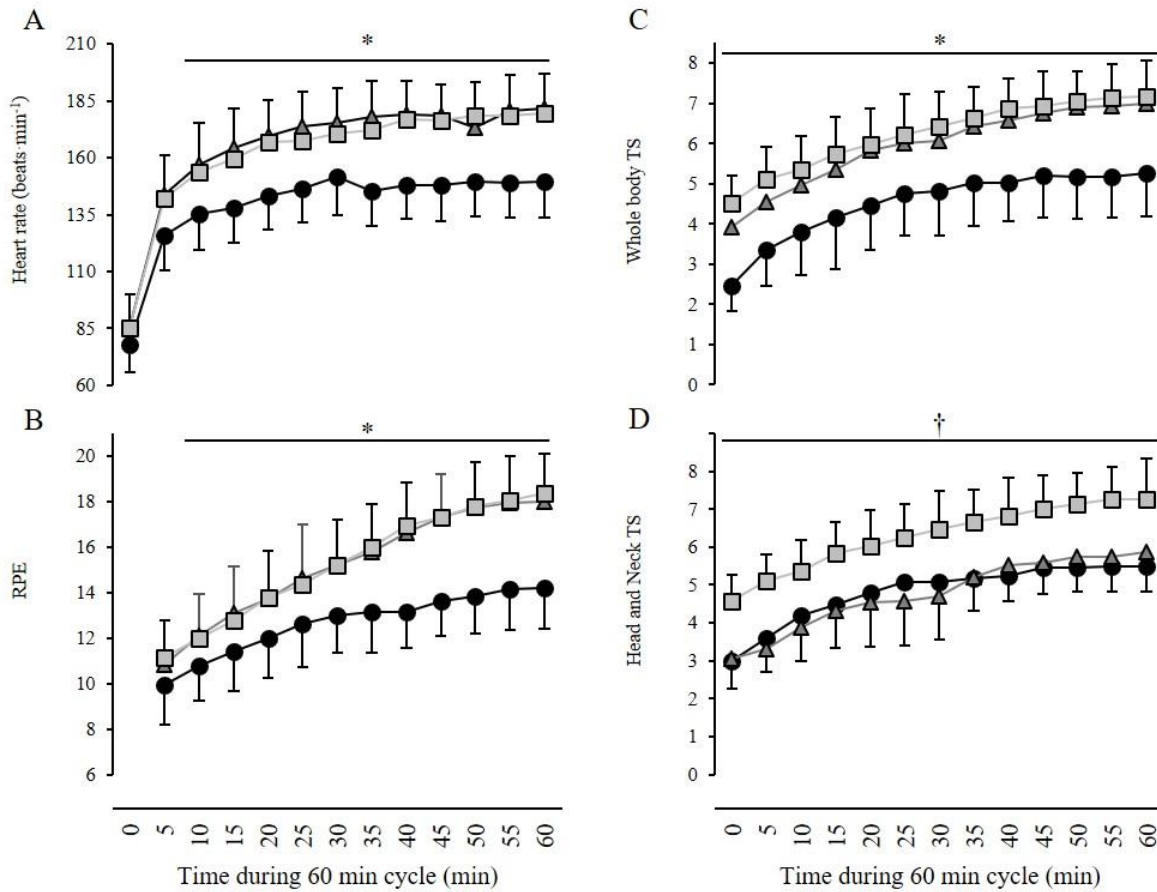

Figure. 2. Rectal (A), skin (B), and neck temperatures (C) recorded during and post 60 min of cycling in three separate environmental conditions: hot (HOT; light grey squares), HOT with head and neck cooling (HOT<sub>cooling</sub>, dark grey triangles), and control (CON, black circles). Data are mean  $\pm$  SD ( $n = 14$ ). Between condition paired differences are denoted by \* (CON < HOT and HOT<sub>cooling</sub>), † (CON and HOT<sub>cooling</sub> < HOT), and ‡ (CON different from HOT<sub>cooling</sub>).

631

632 Figure. 3. Heart rate (A), ratings of perceived exertion (RPE; B), whole body thermal sensation

633 (TS; C) and head and neck TS (D), during 60 min of cycling at 50%  $\dot{V}O_{2peak}$  in three separate

634 environmental conditions: Hot (HOT; light grey squares), HOT with head and neck cooling

635 (HOT<sub>cooling</sub>; dark grey triangles), and control (CON black circles). Data are mean  $\pm$  SD ( $n =$

636 14). Between condition paired differences are denoted by \* (CON < HOT and HOT<sub>cooling</sub>) and

637 † (CON and HOT<sub>cooling</sub> < HOT).

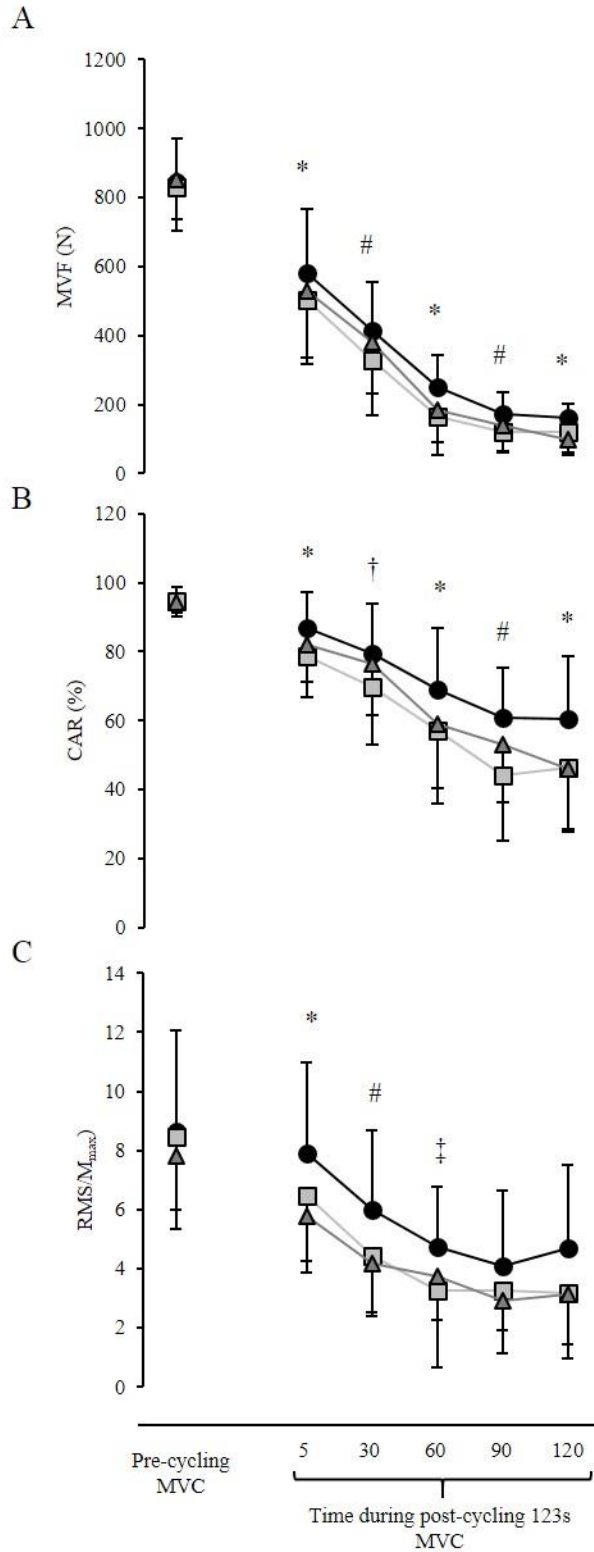

Figure. 4. Maximal voluntary force (MVF; A), central activation ratio (CAR; B) and normalised EMG amplitude at MVF ( $EMG_{MVF}$ , C), of the knee extensors pre-, and during a 123s MVC immediately post- a 60 min cycle in three separate environmental conditions: Hot (HOT, light grey squares), HOT with head and neck cooling (HOT<sub>cooling</sub>, dark grey triangles), and control (CON, black circles). Data are mean  $\pm$  SD ( $n = 14$  except for  $EMG_{MVF}$  where  $n = 13$ ). Between condition paired differences are denoted by \* (CON > HOT and HOT<sub>cooling</sub>), # (CON > HOT), † (CON and HOT<sub>cooling</sub> > HOT), and ‡ (CON > HOT<sub>cooling</sub>).
